1) Cartesian coordinate chart

chart design

- * x-axis steps walked (0-20,000) steps
- * y-axis : calories burned (0-1,000 calories)
- * chart type : scatter plot or line chart

insight :-

- The chart usually shows a positive correlation
- more steps generally result in more calories burned
- it can also identify days with unusually low or high activity

2) Data type classification

<u>variable</u>	<u>data type</u>	<u>Reason</u>
Age	continuous	can include decimal values (20.5 years)
Blood group	Nominal	categories with no order
Classification	ordinal	

- The interpretation depends on how the data is collected

3) Diverging colour scale vs sequential colour scale

⇒ sequential colour scale

uses order from light
to dark

Diverging colour scale

uses two contrasting colours
with neutral or midpoint

Best for low to high values

Best for values above and below
a central value

Shows increasing intensity

Highlights positive and negative

⇒ profit and loss

2) Temperature difference from average

4) ⇒ Shows exponential growth (can)

2) Early growth is visible

⇒ large numbers to not dominate the graph

⇒ Every year appears almost flat

5) Chart design

⇒ angle(θ) : wind direction ($0^\circ - 360^\circ$)

⇒ Radius (r) : wind speed

⇒ Each point : represent one month

⇒ strong wind needs may occur from the southwest

during the monsoon

⇒ winter months may show weaker winds from the northeast.
